

A Scheme Expression is a Scheme List

Scheme programs consist of expressions, which can be:

- Primitive expressions: 2 3.3 true + quotient
- Combinations: (quotient 10 2) (not true)

The built-in Scheme list data structure (which is a linked list) can represent combinations

```
scm> (list 'quotient 10 2)
(quotient 10 2)
scm> (eval (list 'quotient 10 2))
5
```

In such a language, it is straightforward to write a program that writes a program

(Demo)

Discussion Question: Automatically Simplifying Code

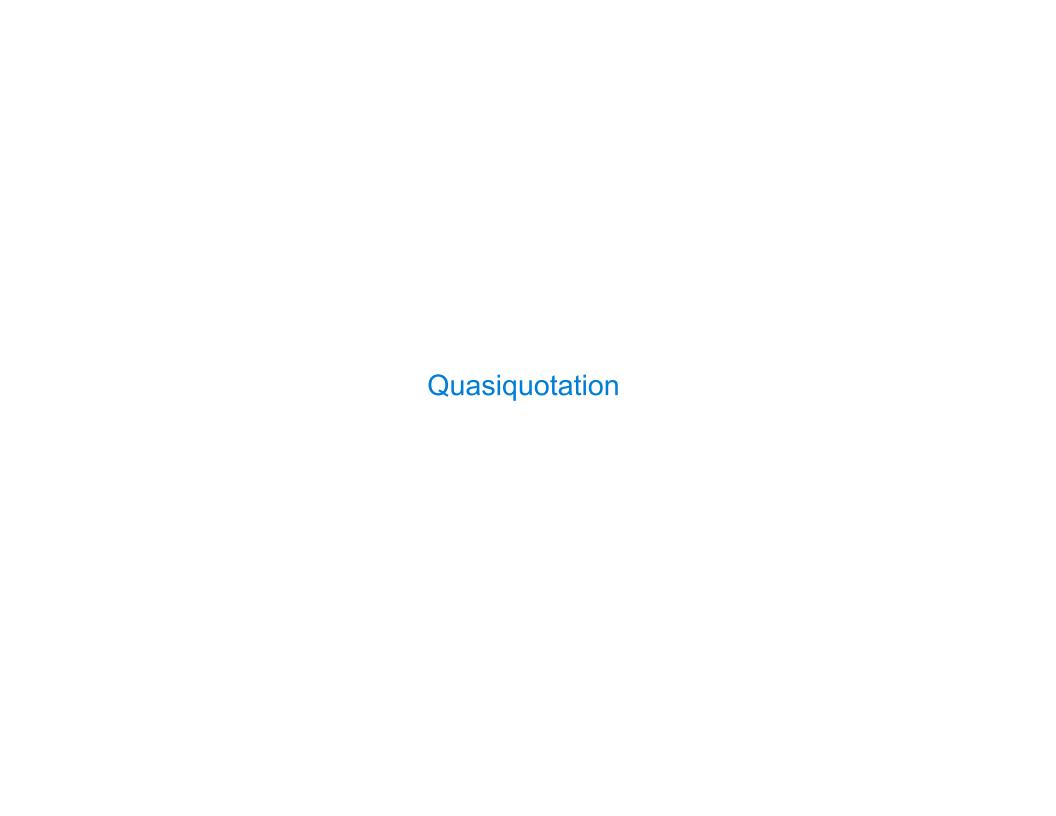

```
SCM> (* 1 2 (* 3 (* 4)) (+ 5 (* 6 (* 7 8))))
8184
scm> (flatten-nested-* '(* 1 2 (* 3 (* 4)) (+ 5 (* 6 (* 7 8)))))
(* 1 2 3 4 (+ 5 (* 6 7 8)))
scm> (* 1 2 3 4 (+ 5 (* 6 7 8)))
8184
scm> (eval (flatten-nested-* '(* 1 2 (* 3 (* 4)) (+ 5 (* 6 (* 7 8))))))
8184
(define (is-*-call expr) (and (list? expr) (equal? '* (car expr)))) ; E.g., (* 3 4)
(define (flatten-nested-* expr); Return an equivalent expression with no nested calls to *
 (if (not (list? expr)) expr
    (let ((expr (map flatten-nested-* expr))); Now expr is (* 1 2 (* 3 4) (+ 5 (* 6 7 8)))
     (if (is-*-call expr)
         (apply append (map (lambda (e) (if (is-*-call e) (cdr e) (list e))) expr))
         expr))))
                                                                    (+ 5 (* 6 7 8))
                                                          (* 3 4)
```

Discussion Question: Printing Evaluations

Define print_evals, which takes a Scheme expression expr that contains only numbers, +, *, if and parentheses. It prints all of the expressions that are evaluated during the evaluation of expr and their values. Print in the order that evaluation completes.

Assume every if expression has three sub-expressions: predicate, consequence, & alternative.

```
scm > (define expr'(* 2 (if (> 2 (+ 1 1)) (+ 3 4) (* 5 6))))
expr
scm> (eval expr)
60
                                                 (define (print-evals expr)
scm> (print-evals expr)
* => #[*]
                                                   (if (list? expr)
2 => 2
                                                       (if (equal? (car expr) _ 'if )
> => #[>]
2 => 2
                                                         (begin
+ => #[+]
1 => 1
                                                           (print-evals (car (cdr expr)))
1 => 1
                                                             (if (eval (car (cdr expr)))
(+ 1 1) => 2
(> 2 (+ 1 1)) => #f
                                                                 (print-evals (car (cdr (cdr expr))))
* => #[*]
5 => 5
                                                                 (print-evals (car (cdr (cdr expr)))))))
6 => 6
                                                         (map print-evals expr) ____ ))
(* 5 6) => 30
(if (> 2 (+ 1 1)) (+ 3 4) (* 5 6)) \Rightarrow 30
(* 2 (if (> 2 (+ 1 1)) (+ 3 4) (* 5 6))) => 60
                                                   (print expr '=> (eval expr)))
```

Quasiquotation

```
There are two ways to quote an expression

Quote: '(a b) => (a b)

Quasiquote: `(a b) => (a b)

Parts of a quasiquoted expression can be unquoted with , to evaluate sub-expressions (define b 4)

Quasiquote: `(a ,(+ b 1)) => (a 5)

Quasiquotation is particularly convenient for generating Scheme expressions:

(define (make-add-lambda n) `(lambda (d) (+ d ,n)))

(make-add-lambda 2) => (lambda (d) (+ d 2))
```

8

Discussion Question: Fact-Exp

Use quasiquotation to define **fact-expr**, a procedure that takes an integer n and returns a nested multiplication **expr**ession that evaluates to n **fact**orial.
